RESEARCH

The Information in Option Strike Price Introductions

(Job Market Paper)

Abstract: I examine the information content of option introductions with new strike prices. I find that stocks with options introduced above the prevailing maximum strike price outperform those with options introduced below the prevailing minimum strike price by up to 6% over the following 12 months. While this result is neither explained by stock-price momentum nor a variety of other documented stock and option variables, it is stronger for stocks with high informed trading intensity and high option-to-stock volume ratio, consistent with informed traders disguising their trades in high volume. The new out-of-the-money options with higher leverage are actively traded after introduction. The evidence suggests that informed investors can benefit from the introduction of new strike prices that enables cost-effective leverage.

Narrative Momentum

(with Xiaoxia Lou, Gideon Ozik, Ronnie Sadka)

Abstract: This paper advances that investors underreact to economic narratives. Using a vast dataset of digital media sources collected point-in-time since 2012, coverage intensities of roughly 350 narratives are quantified, and corresponding narrative-mimicking, long-short portfolios are constructed using stock narrative betas. Narrative-mimicking portfolios of recently rising narrative intensities outperform those of declining intensities by about 8% annually, controlling for standard risk factors. Neither stock nor factor price momentum explains narrative momentum, which is stronger for slowly trending narratives. Furthermore, analysts tend to underreact to narrative-sensitive stocks. Additional results highlight the importance of considering the discourse among sources beyond traditional, general media.

Market Cycle Momentum in Anomalies

(Solo-authored)

Abstract: Factors that performed well in the past bear market tend to perform well in the current one. Using ex-ante information to define market cycles, I find that market cycle-dependent returns can explain the cross-section of expected returns of the 47 factor portfolios. A long-short portfolio that exploits this finding has a 5-factor alpha of 0.7% per month during 1963-2019. The results are not explained by factor momentum, investor sentiment, or the mean factor portfolio. My results suggest that the cross-section of factors is better explained by differences in risk profiles across business cycles rather than differences in mispricing.
